

Proseminar “The Rust Programming Language”

Summer Term 2017

Garbage Collection & Reference Counting

Clemens Ruck & Alex Egger
Technische Universität München

July 12, 2017

Abstract

The aim of this paper is to give a broad overview of memory management techniques, and to compare them to the method of using ownership and lifetimes as employed in the Rust programming language. Further it aims to give an overview of the possible techniques in the Rust language.

1 Introduction

When talking about memory management one must first understand where in memory a variable can even be stored. In general there may be three places a variable could be:

- Static memory
- Stack
- Heap

Memory can be *statically allocated*, which means it is placed directly in the binary file of the program. The “static” here means the memory cannot be changed. Let us look at the simple C program provided in

```
1 #include <stdio.h>
2
3 const static char *s = "Hello, World!";
4
```

```
5 int main(void) {
6     printf("%s\n", s);
7     return 0;
8 }
```

The introduction of a scientific work usually consists of the following parts:

- motivation,
- issues or drawbacks with existing solutions of a problem at hand,
- overview of new contribution and rest of the paper.

In the motivation you should explain why a given topic is interesting at all, and also, why solutions are important from a scientific point of view. There already may be a lot of existing solutions. Thus, it is important for the reader to understand the issues with these solutions, and why they are not enough for e.g. a specific scenario. Often, concrete examples are quite useful in providing a motivation, as well as providing a running example, that can be picked up later on in the main part. After the motivational example, you should explain the basic idea of your new contribution to solve the problem at hand, and give a short overview (only a slight hint) of how this works.

```

1 #include <iostream>
2 void main(void){
3     std::cout << "simple code example";
4 }

```

Figure 1: A very simple C++ code fragment

Related Work

Here, you elaborate on how this approach differs from other existing solutions – if not in general, then illustrate the scenario, in which the approach is beneficial. This subsection also offers room for introducing related or alternative approaches to this approach, and establishes a kind of state of the art. This might even incorporate solution approaches in other fields, if the setting is comparable to this thesis. Translated to topics in programming languages, this would mean e.g. similar solutions in other programming languages. Ultimately, however, this should culminate in explicitly formulating the *thesis statement* [7]:

- what is the unique core contribution of this specific approach
- in not more than 3 itemss
- this should be thought of the basic information, that the reader should take away from your paper

This concept of unique core contributions is in seminar papers, what in research papers is usually the *Research Question* [5]. As the seminar paper is usually meant to be a piece of work, that teaches students to write academic papers, the usual guides for general scientific writing like the work of Turabian [8] or the more computer science centric approach of Zobel [9] can also be applied to seminar papers. Finally, a short overview to the structure of the rest of the work should be provided, which may indicate the most important points. As any idea or solution proposed must be shown to be valid and useful, every scientific paper must have some evaluation and/or discussion. It may to useful to select important results, and mention them already

Figure 2: The caption explaining what can be seen in the image/figure. Readers often read captions first if they do not have much time. Thus, it is important to find a good short explanation.

as last part of the introduction, as motivation for the reader to read on. In summary, a good introduction creates interest for the topic and proposed new contributions that the reader cannot wait to read on.

2 Paper organization

The main part of a scientific paper is organized in a somewhat similar way each time:

1. You announce, that you will tell about something in the *abstract*
2. You introduce to what you did in the *introduction*
3. You clarify the amount of your specific contribution in the *related work*
4. You make the paper well-founded, by introducing necessary standards in the *basics part*
5. You actually tell about what you did in the *main part*
6. *Optional, if possible:* You evaluate in as neutral a way as possible what You have done in the *evaluation*
7. You summarize, and finally draw conclusions on what you have done in the *conclusion*
8. You sketch, what could be achieved next, based on this work in the *future work*

Figure 3: A nice caption. The larger width allows for more text without taking too much space.

3 Basic Rules for Using Latex

Latex is the system of choice for scientific publications. Papers are expected to be delivered in Latex form, scientific publishers even require you to make use of their templates [4, 2]. We thus strongly encourage students to get to grips with Latex. As programmers, You will most likely enjoy the workflow of a text processor like Latex anyway. The following is meant as a demonstration of the capabilities and the source code, that is necessary to produce this output. You may use the source code of this seminar paper as a template, if you wish.

First, we want to refer to the figures and the introduction. See Fig.2 for the first floating figure with column width, and Fig.3 for the one using the full page width. And here, we want to put a reference to the introduction which is Section 1.

In translating this template from German to English, I decided to stop here. There is not really much to get from the German text following. Anything Latex-related can also be looked up on the net. There is a *huge* number of tutorials, and so on.

Please do not use too much different font sizes and styles. It should be completely enough to go to *italic mode* for emphasizing something, such as newly introduced terms. You can refer to other parts of your paper (e.g. see Sec. 1). Quoting in Latex is done “this way”. Further, you may have

problems with punctuation characters. Most of them just need to be prefixed by a backslash, for others you may temporarily switch to math mode: \$ & % # { } [] - @ § < > \ @ ~ /
Talking about math mode: you can do some very nice things this way:

$$a^2 + b^2 = c^2 \quad (1)$$

Again, referring to this equation is easy (see Eq. 1). If you do not need numbering for equations, use the *displaymath* environment:

$$x_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Short equations simply can be used within the regular text flow, such as with $x \rightarrow \infty$. Obviously, math is fun with Latex.

Enumerations

Enumerations using bullet points:

- this is the first item of this list of interesting facts,
- second item,
- and the last one.

They also can be numbered:

1. item one,

2. item two,
3. item three.

As shown, numbers always should be written out in the text, unless they belong to a title or a formula.

4 Literature

At the end of your paper, you should have a nice list of used literature. For scientific papers, this actually is needed. You always use other works as base for your own. Usually, you are not the only one thinking about a given difficult problem, so there is always related work which *must* be cited if known to the author.

Further, if you want to copy relevant sentences from an original paper, you *have* to cite them correctly, for example in this way:

“I think there is a world market for maybe five computers.” (T.J. Watson, IBM, 1943)

However, in computer science, direct citations are uncommon if not even considered bad style – with the notable exception of lemmas and theorems.

Much more common is the indirect citation. Here, the cited work (especially all the regular text) must be written/phrased by you. If you write about some results or fact stated in another paper, you should refer to it. The ‘Analytical Engine’ — a mechanical calculation machine — created by Charles Babbage in the year 1838 was based on the decimal system [6].

You can find new sources for scientific topics quite comfortably via DBLP Computer Science Bibliography [3]. This site not only acts as a registry for almost all publications in computer scientific journals and conferences, but also provides you with correctly formatted *bibtex*-entries, ready to be integrated into your seminar papers *bib*-file.

5 Figures and Tables

No need to understand the following text.

Figures can span either one column (see Fig. 2) or the full page width (see Fig. 3). Latex automatically tries to find the best place for these floating figures. To influence that, you may move the figure a bit to the front of your text. As can be seen in Fig. 2, using raster images usually results in quite bad quality. Better use vector formats: draw the figures with *inkscape* [1], and save them as PDF or SVG. As example of this procedure, see Fig. 3).

Similar to figures, tables can be referred to in the text (see Tab. 5). However, sometimes it is useful to embed tables directly in the regular text flow:

	Column 1	Column 2
Row 1		
Row 1		

6 Summary

The summary shortly repeats the core ideas and results from the previous text. If the reader has problems understanding the summary he knows that he should go back to the relevant sections. Thus, the last section should consist of:

- a summary,
- an evaluation of what was done, importance of this work,
- what is left, what still needs to be done,
- short outlook into the future.

Last but not least, we can explain anything missing yet in the evaluation done in this paper. This allows to refer to what readers can expect from authors in the future.
